1 Introduction

Sassafras is a shell mode program for data analysis.

Example

A die, which may be loaded, is tossed six times. The observed point values are one to six. Compute a 95% confidence interval for the true mean μ given the observed data.

```
data ;  
input y ;  
datalines ;  
1  
2  
3  
4  
5  
6  
;  
proc means clm ;
```

The following result is displayed.

Variable	95% CLM MIN	95% CLM MAX
Y	1.537	5.463

Here is the same result using R.

```
> y = c(1,2,3,4,5,6)  
> t.test(y)
```

One Sample t-test

```
data: y  
t = 4.5826, df = 5, p-value = 0.005934  
alternative hypothesis: true mean is not equal to 0  
95 percent confidence interval:  
1.536686 5.463314
```

2 Data Step

A data step is used to get data into the program.

```
data name ;  
infile "filename" dlm="delims" firstobs=n ;  
input list ;  
var = expression ;  
datalines ; data ;
```

Notes

1. *name* is optional.
2. The `dlim` and `firstobs` settings are optional.
3. *delims* is a sequence of delimiter characters. The default is tab, comma, and space.
4. *n* is the starting input record number. Use `firstobs=2` to skip a header in the data file.
5. *list* is a list of variable names separated by spaces. For each categorical variable place a \$ after the variable name.
6. Optional *var = expression* statements create new vectors in the data set.
7. The `datalines` statement is followed by observational data. At the end of the data a semicolon terminates the statement.

Example 1

The following example is a minimalist data step with in-line data.

```
data ;  
input y ;  
datalines ;  
1  
2  
3  
4  
5  
6  
;
```

Example 2

Use @@ at the end of an input statement to allow multiple values on an input line.

```
data ;  
input y @@ ;  
datalines ;  
1 2 3  
4 5 6  
;
```

Example 3

A dollar sign after an input variable indicates that the variable is categorical instead of numerical.

```
data ;
input trt $ y @@ ;
datalines ;
A 6    A 0    A 2    A 8    A 11
A 4    A 13   A 1    A 8    A 0
B 0    B 2    B 3    B 1    B 18
B 4    B 14   B 9    B 1    B 9
C 13   C 10   C 18   C 5    C 23
C 12   C 5    C 16   C 1    C 20
;
```

Example 4

An infile statement is used to read data from a file.

```
data ;
input color $ x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 x11 y ;
infile "wine.txt" ;
```

Example 5

Expressions in a data step create new data vectors. The following example creates Y2 which is the input vector Y squared element-wise.

```
data ;
input color $ x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 x11 y ;
infile "wine.txt" ;
y2 = y ** 2 ;
```

3 Anova Procedure

The anova procedure fits a classification model to data using ordinary least squares. The response variable must be numeric and the explanatory variables must be categorical.

```
proc anova data=name ;  
model y = list ;  
means list ;  
means list / lsd ttest alpha=value ;
```

Notes

1. *data=**name* is optional. The default is data from the most recent data step.
2. *y* is the response variable which must be numeric.
3. *list* is one or more explanatory variables separated by spaces. The explanatory variables must be categorical. Interaction terms are specified using the syntax *A*B*.
4. The means statement can include one or more of the following options.

lsd	Compare treatment means using least significance difference
ttest	Compare treatment means using two sample <i>t</i> -test
alpha	Set the level of significance. Default is 0.05.

Example

```
data ;  
input trt $ y @@ ;  
datalines ;  
A 6    A 0    A 2    A 8    A 11  
A 4    A 13   A 1    A 8    A 0  
B 0    B 2    B 3    B 1    B 18  
B 4    B 14   B 9    B 1    B 9  
C 13   C 10   C 18   C 5    C 23  
C 12   C 5    C 16   C 1    C 20  
;  
  
proc anova ;  
model y = trt ;  
means trt / lsd ttest ;
```

The following result is displayed.

Analysis of Variance

Mean response table

The confidence interval for a treatment mean is computed as follows.

$$\bar{y}_i \pm t(1 - \alpha/2, dfe) \cdot \sqrt{\frac{MSE}{n_i}}$$

Recall that MSE is an estimate of model variance. From the anova table

Error	27	995.10000000	36.85555556
-------	----	--------------	-------------

we obtain

$$MSE = 36.85555556$$

$$dfe = 27$$

Using R, the confidence interval for the mean of treatment A can be checked as follows.

```
> MSE = 36.8556
> dfe = 27
> t = qt(0.975,dfe)
> 5.3 - t * sqrt(MSE/10)
[1] 1.360934
> 5.3 + t * sqrt(MSE/10)
[1] 9.239066
```

Least significant difference test

The least significant difference of two means \bar{y}_i and \bar{y}_j is

$$LSD_{ij} = t(1 - \alpha/2, dfe) \cdot \sqrt{MSE \cdot \left(\frac{1}{n_i} + \frac{1}{n_j}\right)}$$

The corresponding confidence interval is

$$\bar{y}_i - \bar{y}_j \pm LSD_{ij}$$

Two sample *t*-test

The two sample *t*-test is computed as follows.

$$\begin{aligned} SSE &= \widehat{Var}_i \cdot (n_i - 1) + \widehat{Var}_j \cdot (n_j - 1) \\ dfe &= n_i + n_j - 2 \\ MSE &= \frac{SSE}{dfe} \\ SE &= \sqrt{MSE \cdot \left(\frac{1}{n_i} + \frac{1}{n_j}\right)} \\ t^* &= \frac{\bar{y}_i - \bar{y}_j}{SE} \end{aligned}$$

SSE is the sum of squares error recovered from variance estimates, *dfe* is the degrees of freedom error, *MSE* is mean square error, *SE* is the standard error, and *t** is the test statistic. The confidence interval is

$$\bar{y}_i - \bar{y}_j \pm t(1 - \alpha/2, dfe) \cdot SE$$

The null hypothesis is that the two treatment means are equal.

$$H_0 : \bar{y}_i = \bar{y}_j$$

If $|t^*|$ is greater than the critical value $t(1 - \alpha/2, dfe)$, or equivalently, if the confidence interval does not cross zero, then reject H_0 and conclude that the treatment means are not equal. The following R session uses the above equations to duplicate the Sassafras result for treatments A and B.

```
> YA = c(6,0,2,8,11,4,13,1,8,0)
> YB = c(0,2,3,1,18,4,14,9,1,9)
> sse = var(YA) * (length(YA) - 1) + var(YB) * (length(YB) - 1)
> dfe = length(YA) + length(YB) - 2
> mse = sse / dfe
> se = sqrt(mse * (1 / length(YA) + 1 / length(YB)))
> t = (mean(YA) - mean(YB)) / se
> mean(YA) - mean(YB) - qt(0.975,dfe) * se
[1] -5.922307
> mean(YA) - mean(YB) + qt(0.975,dfe) * se
[1] 4.322307
> 2 * (1 - pt(abs(t),dfe))
[1] 0.746606
```

The same result is obtained with the t-test function.

```
> t.test(YA,YB,var.equal=TRUE)
```

Two Sample t-test

```
data:  YA and YB
t = -0.3281, df = 18, p-value = 0.7466
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
 -5.922307  4.322307
sample estimates:
mean of x mean of y
    5.3      6.1
```

4 Means Procedure

The means procedure prints statistics about a data set.

```
proc means data=name alpha=value maxdec=n stats ;  
var list ;  
class list ;
```

Notes

1. The settings that follow the **means** keyword are optional. The settings can appear in any order.
2. If **data** is not specified then the default is data from the most recent data step.
3. **alpha** sets the level of significance. The default is 0.05.
4. **maxdec** sets the decimal precision in the output. n ranges from 0 to 8. The default is 3.
5. **stats** is a list of statistics keywords from the following table.

clm	Confidence limits of the mean
max	Maximum value
mean	Mean value
min	Minimum value
n	Number of observations
range	$\text{max} - \text{min}$
std	Standard deviation s
stddev	Another keyword for s
stderr	Standard error s/\sqrt{n}
var	Variance s^2

If **stats** is not specified then the default list is **n mean std min max**.

6. The optional **var** statement specifies which variables to print. The default is all variables. Variable names in *list* are separated by spaces.
7. The optional **class** statement prints statistics for each level of the categorical variables in *list*. Variable names in *list* are separated by spaces.

Example 1

The following example reads in the wine¹ data set and shows the default action of `proc means`.

¹P. Cortez, A. Cerdeira, F. Almeida, T. Matos and J. Reis. *Modeling wine preferences by data mining from physicochemical properties*. In Decision Support Systems, Elsevier, 47(4):547-553, 2009.

```
data wine ;
input color $ x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 x11 y ;
infile "wine.txt" ;

proc means ;
```

The following result is displayed.

Variable	N	Mean	Std Dev	Minimum	Maximum
X1	6497	7.215	1.296	3.800	15.900
X2	6497	0.340	0.165	0.080	1.580
X3	6497	0.319	0.145	0.000	1.660
X4	6497	5.443	4.758	0.600	65.800
X5	6497	0.056	0.035	0.009	0.611
X6	6497	30.525	17.749	1.000	289.000
X7	6497	115.745	56.522	6.000	440.000
X8	6497	0.995	0.003	0.987	1.039
X9	6497	3.219	0.161	2.720	4.010
X10	6497	0.531	0.149	0.220	2.000
X11	6497	10.492	1.193	8.000	14.900
Y	6497	5.818	0.873	3.000	9.000

Example 2

The following example adds a var statement to show Y by itself. Also, the desired statistics are specified.

```
data wine ;
input color $ x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 x11 y ;
infile "wine.txt" ;

proc means n mean clm ;
var y ;
```

The following result is displayed.

Variable	N	Mean	95% CLM MIN	95% CLM MAX
Y	6497	5.818	5.797	5.840

Example 3

The following example adds a class statement to show statistics for each wine color.

```
data wine ;
input color $ x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 x11 y ;
infile "wine.txt" ;

proc means n mean clm ;
var y ;
class color ;
```

The following result is displayed.

COLOR	Variable	N	Mean	95% CLM MIN	95% CLM MAX
red	Y	1599	5.636	5.596	5.676
white	Y	4898	5.878	5.853	5.903

5 Print Procedure

The print procedure prints data in a data set.

```
proc print data=name ;  
var list ;
```

Notes

1. `data=name` is optional. The default is data from the most recent data step.
2. The optional `var` statement specifies which variables to print. The default is all variables. Variable names in *list* are separated by spaces.

Example

The following example reads a data set and prints it.

```
data ;  
input trt $ y @@ ;  
datalines ;  
A 6    A 0    A 2    A 8    A 11  
A 4    A 13   A 1    A 8    A 0  
B 0    B 2    B 3    B 1    B 18  
B 4    B 14   B 9    B 1    B 9  
;  
  
proc print ;
```

The following result is displayed.

Obs	TRT	Y
1	A	6
2	A	0
3	A	2
4	A	8
5	A	11
6	A	4
7	A	13
8	A	1
9	A	8
10	A	0
11	B	0
12	B	2
13	B	3
14	B	1
15	B	18
16	B	4
17	B	14
18	B	9
19	B	1
20	B	9

6 Reg Procedure

The reg procedure fits a linear model to data using ordinary least squares. The response variable must be numeric. For models with no intercept, anova results will differ from R. This is because R switches to uncorrected sums of squares for models with no intercept.

```
proc reg data=name ;  
model y = list ;  
model y = list / noint ;
```

Notes

1. `data=name` is optional. The default is data from the most recent data step.
2. `y` is the response variable which must be numeric.
3. `list` is a list of explanatory variables separated by spaces. If functions of explanatory variables are required then they must be defined in the data step.
4. The `noint` option fits a linear model with no intercept term.

Example 1

The following example reads in the wine data set and fits a linear model with no intercept term.

```
data ;  
input color $ x1 x2 x3 x4 x5 x6 x7 x8 x9 x10 x11 y ;  
infile "wine.txt" ;  
  
proc reg ;  
model y = color x1 / noint ;
```

The following result is displayed.

Analysis of Variance					
	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	72.79210	36.39605	48.42	0.0000
Error	6494	4880.89360	0.75160		
Total	6496	4953.68570			
Root MSE		0.86695	R-Square	0.0147	
Dependent Mean		5.81838	Adj R-Sq	0.0144	
Coeff Var		14.90018			
Parameter Estimates					
	Estimate	Std Err	t Value	Pr > t	
COLOR red	5.77309	0.08194	70.45	0.0000

X1	-0.01647	0.00950	-1.73	0.0829	

Example 2

The following exercise is from *Econometrics*². Using data from a 1963 paper by Marc Nerlove, estimate parameters for the model

$$\log(\text{COST}) = \beta_0 + \beta_1 \log(\text{KWH}) + \beta_2 \log(\text{PL}) + \beta_3 \log(\text{PF}) + \beta_4 \log(\text{PK}) + \varepsilon$$

where COST is production cost, KWH is kilowatt hours, PL is price of labor, PF is price of fuel, and PK is price of capital.

```
data ;
infile "nerlove.txt" ;
input COST KWH PL PF PK ;
LCOST = log(COST) ;
LKWH = log(KWH) ;
LPL = log(PL) ;
LPF = log(PF) ;
LPK = log(PK) ;

proc reg ;
model LCOST = LKWH LPL LPF LPK ;
```

The following result is displayed.

Analysis of Variance					
	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	4	269.51482	67.37870	437.69	0.0000
Error	140	21.55201	0.15394		
Total	144	291.06683			
	Root MSE	0.39236	R-Square	0.9260	
	Dependent Mean	1.72466	Adj R-Sq	0.9238	
	Coeff Var	22.74969			
Parameter Estimates					
	Estimate	Std Err	t Value	Pr > t	
Intercept	-3.52650	1.77437	-1.99	0.0488	
LKWH	0.72039	0.01747	41.24	0.0000	
LPL	0.43634	0.29105	1.50	0.1361

LPK	-0.21989	0.33943	-0.65	0.5182	

The following code can be pasted into R to obtain a similar result.

```
d = read.table("nerlove.txt")
lcost = log(d[,1])
lkwh = log(d[,2])
lpl = log(d[,3])
lpf = log(d[,4])
lpk = log(d[,5])
m = lm(lcost ~ lkwh + lpl + lpf + lpk)
summary(m)
```

The following result is displayed in R.

²Hansen, Bruce E. *Econometrics*. www.ssc.wisc.edu/~bhansen

```

Call:
lm(formula = lcost ~ lkwh + lpl + lpf + lpk)

;

proc reg ;
model LV = LG LH ;

```

The following result is displayed.

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	1.53213547	0.76606773	613.19	0.0000
Error	28	0.03498056	0.00124931		
Total	30	1.56711603			
Root MSE		0.03535	R-Square	0.9777	
Dependent Mean		1.42133	Adj R-Sq	0.9761	
Coeff Var		2.48679			

Parameter Estimates				
Parameter	Estimate	Std Err	t Value	Pr > t
(Intercept)	-2.88007	0.34734	-8.29	0.0000
log(Girth)	1.98265	0.07501	26.43	0.0000
log(Height)	1.11712	0.20444	5.46	0.0000

Let us see if the above parameters correspond to the volume of a cone given by

$$V = \frac{\pi}{12}d^2h$$

where d is the diameter (girth) and h is the height of the cone. The model from the regression is

$$\log V = -2.88 + 1.98 \log d + 1.12 \log h$$

Take the antilog of both sides and obtain

$$V = 0.00132 \times d^{1.98} \times h^{1.12}$$

The exponents resemble the volume formula but the overall coefficient 0.00132 is two orders of magnitude smaller than $\pi/12 \approx 0.262$. It turns out the discrepancy is due to the units of measure. Girth is measured in inches while height and volume are measured in feet. To convert girth from inches to feet requires a factor of 1/12. Hence the leading coefficient should be

$$\frac{\pi}{12} \times \frac{1}{144} \approx 0.00182$$

which is in the ballpark of 0.00132 from the regression model.

Let us compare the Reg results to R. The following block of code can be pasted directly into the R shell prompt.

```
d=log10(trees[,1])
h=log10(trees[,2])
V=log10(trees[,3])
m=lm(V~d+h)
summary(m)
```

This is the R result, which matches Reg.

7 Review

Analysis of Variance

The components of an analysis of variance table are computed as follows.

	DF	SS	Mean Square	F-value	p-value
Model	$p - 1$	SSR	$MSR = SSR/(p - 1)$	$F^* = MSR/MSE$	$1 - F(F^*, p - 1, n - p)$
Error	$n - p$	SSE	$MSE = SSE/(n - p)$		
Total	$n - 1$	SST			

In the table, n is the number of observations and p is the number of model parameters including the intercept term if there is one. The sums of squares are computed as follows.

$$\begin{aligned} SSR &= \sum (\hat{y}_i - \bar{y})^2 \\ SSE &= \sum (y_i - \hat{y}_i)^2 \\ SST &= \sum (y_i - \bar{y})^2 \end{aligned}$$

Recall that MSE is an estimate of model variance.

$$MSE = \hat{\sigma}^2$$

A simple way to model the response variable is to use the average \bar{y} . The p -value above indicates whether or not the regression model is better than \bar{y} . The null hypothesis is that the regression model is no better than the average, that is

$$H_0 : SST = SSE$$

The test for H_0 is known as an omnibus test because an equivalent hypothesis is

$$H_0 : \beta_1 = \beta_2 = \cdots = \beta_{p-1} = 0$$

Under H_0 we have $SSR = 0$ hence another equivalent hypothesis is

$$H_0 : F^* = 0$$

The test statistic F^* is used because it has a well-known distribution. Recall that the p -value is (loosely) the probability that H_0 is true. Hence for small p -values, reject H_0 and conclude that the regression model is better than \bar{y} .

Confidence interval of the mean

The confidence interval of the mean is

$$\bar{x} \pm t_{1-\alpha/2, n-1} \frac{s}{\sqrt{n}}$$

where \bar{x} is the observed mean, s is the observed standard deviation, n is the number of observations, and $t_{1-\alpha/2, n-1}$ is the quantile function. In R, the confidence interval of the mean of 1:10 can be computed as follows.

```

> x = 1:10
> n = length(x)
> alpha = 0.05
> mean(x) - qt(1-alpha/2,n-1) * sd(x)/sqrt(n)
[1] 3.334149
> mean(x) + qt(1-alpha/2,n-1) * sd(x)/sqrt(n)
[1] 7.665851

```

Alternatively, the `t.test` function can be used.

```

> t.test(1:10)

One Sample t-test

data:  1:10
t = 5.7446, df = 9, p-value = 0.0002782
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
 3.334149 7.665851
sample estimates:
mean of x
      5.5

```

Recall that the quantile function is the inverse of the cumulative distribution function. Let F be the cumulative distribution function. Then

$$F(t_{1-\alpha/2,n-1}) = 1 - \alpha/2$$

For example, in R we have

```

> t = qt(0.975,8)
> t
[1] 2.306004
> pt(t,8)
[1] 0.975

```

8 Anova results

Consider the following anova program and its output. Note that the least significant difference test has more power than the t -test.

```

C	B	6.200000	-0.067653	12.467653	2.08	0.0523

Let us take a closer look at the analysis of variance table.

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	293.60000000	146.80000000	3.98	0.0305
Error	27	995.10000000	36.85555556		
Total	29	1288.70000000			

This is how the table values are computed where n is the number of observations and p is the number of model parameters.

Source	DF	Sum of Squares	Mean Square	F-value	p-value
Model	$p - 1$	SSR	$MSR = SSR/(p - 1)$	$F^* = MSR/MSE$	$1 - F(F^*, p - 1, n - p)$
Error	$n - p$	SSE	$MSE = SSE/(n - p)$		
Total	$n - 1$	SST			

For the following sum of squares calculations, y are observed values and \hat{y} are predicted values.

$$SSR = \sum (\hat{y}_i - \bar{y})^2 = SST - SSE$$

$$SSE = \sum (y_i - \hat{y}_i)^2$$

$$SST = \sum (y_i - \bar{y})^2$$

The p -value in the anova table is used for checking that the regression model is better than the mean \bar{y} . The null hypothesis is that the model is no better than the mean, that is

$$H_0 : SSE = SST$$

Under H_0 we have $SSR = 0$ hence $MSR = 0$ and

$$H_0 : F^* = 0$$

Recall that the p -value is (loosely) the probability that H_0 is true. Hence for small p -values, reject H_0 and conclude that the regression model is better than the mean.

Let us take a closer look at the mean response table.

Mean Response				
TRT	N	Mean Y	95% CI MIN	95% CI MAX
A	10	5.300000	1.360937	9.239063
B	10	6.100000	2.160937	10.039063
C	10	12.300000	8.360937	16.239063

Recall that the confidence interval for a treatment mean is

$$\bar{y} \pm t(1 - \alpha/2, \text{dfe}) \times \text{SE}, \quad \text{SE} = \sqrt{\frac{\text{MSE}}{n}}$$

where SE is standard error and MSE (mean square error) is estimated model variance. From the analysis of variance table at the top of the output we have

Source	DF	Sum of Squares	Mean Square
Error	27	995.1000000	36.85555556

Hence

$$\text{dfe} = 27, \quad \text{MSE} = 36.85555556$$

The confidence interval for the mean of treatment A can be checked by typing the following into R.

```
ybar = 5.3
n = 10
MSE = 36.85555556
dfe = 27
alpha = 0.05
SE = sqrt(MSE / n)
t = qt(1 - alpha/2, dfe) * SE
ybar - t
ybar + t
```

R prints the following results.

```
[1] 1.360937
[1] 9.239063
```

The R results match the mean response table for treatment A.

TRT	N	Mean Y	95% CI MIN	95% CI MAX
A	10	5.300000	1.360937	9.239063

Let us take a closer look at the least significant difference table.

Least Significant Difference Test						
TRT	TRT	Delta Y	95% CI MIN	95% CI MAX	t Value	Pr > t
A	B	-0.800000	-6.370677	4.770677	-0.29	0.7705

The least significant difference of two treatment means \bar{y}_A and \bar{y}_B is

$$\text{LSD} = t(1 - \alpha/2, \text{dfe}) \times \text{SE}, \quad \text{SE} = \sqrt{\text{MSE} \times \left(\frac{1}{n_A} + \frac{1}{n_B} \right)}$$

The corresponding confidence interval is

$$(\bar{y}_A - \bar{y}_B) \pm \text{LSD}$$

The confidence interval in the LSD table can be checked by typing the following into R.

```
ybarA = 5.3
ybarB = 6.1
nA = 10
nB = 10
MSE = 36.85555556
dfe = 27
alpha = 0.05
SE = sqrt(MSE * (1/nA + 1/nB))
LSD = qt(1 - alpha/2, dfe) * SE
ybarA - ybarB - LSD
ybarA - ybarB + LSD
```

R prints the following results.

```
[1] -6.370677
[1] 4.770677
```

The R results match the confidence interval in the LSD table.

TRT	TRT	Delta Y	95% CI MIN	95% CI MAX	t Value	Pr > t
A	B	-0.800000	-6.370677	4.770677	-0.29	0.7705

Let us take a closer look at the t -test table.

Two Sample t-Test						
TRT	TRT	Delta Y	95% CI MIN	95% CI MAX	t Value	Pr > t
A	B	-0.800000	-5.922307	4.322307	-0.33	0.7466

The t -test confidence interval is

$$(\bar{y}_A - \bar{y}_B) \pm t(1 - \alpha/2, \text{dfe}) \times \text{SE}$$

where

$$\text{SE} = \sqrt{\frac{\text{SSE}}{\text{dfe}} \times \left(\frac{1}{n_A} + \frac{1}{n_B} \right)}, \quad \text{SSE} = \sum (y_A - \bar{y}_A)^2 + \sum (y_B - \bar{y}_B)^2$$

and

$$\text{dfe} = n_A + n_B - 2$$

The confidence interval can be checked by typing the following into R.

```
yA = c(6,0,2,8,11,4,13,1,8,0)
yB = c(0,2,3,1,18,4,14,9,1,9)
nA = length(yA)
nB = length(yB)
dfe = nA + nB - 2
SSE = var(yA) * (nA - 1) + var(yB) * (nB - 1)
MSE = SSE / dfe
SE = sqrt(MSE * (1/nA + 1/nB))
alpha = 0.05
t = qt(1 - alpha/2, dfe) * SE
mean(yA) - mean(yB) - t
mean(yA) - mean(yB) + t
```

R prints the following result which matches the above t -test table.

```
[1] -5.922307
[1] 4.322307
```

R's t -test function gives the same result.

```
t.test(yA,yB,var.equal=TRUE)
```

```
Two Sample t-test
```

```
data: yA and yB
t = -0.32812, df = 18, p-value = 0.7466
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
 -5.922307 4.322307
```
