From “V minus A” theory we have the following formula for muon lifetime  $\tau$ .

$$\tau = \frac{96\pi^2 h}{G_F^2 (m_\mu c^2)^5}$$

Symbol  $G_F$  is Fermi coupling constant,  $m_\mu$  is muon mass.

From NIST<sup>2</sup> we have

$$\begin{aligned} G_F &= 1.1663787 \times 10^{-5} \text{ GeV}^{-2} \\ m_\mu &= 1.883531627 \times 10^{-28} \text{ kilogram} \\ h &= 6.62607015 \times 10^{-34} \text{ joule second (exact)} \\ c &= 299792458 \text{ meter second}^{-1} \text{ (exact)} \\ 1 \text{ eV} &= 1.602176634 \times 10^{-19} \text{ joule (exact)} \end{aligned}$$

Hence

$$\tau = 2.18735 \times 10^{-6} \text{ second}$$

The result is a bit smaller than the PDG value.

$$\frac{\tau}{2.1969811 \times 10^{-6} \text{ second}} = 0.9956$$

A muon decays into a muon neutrino, an electron anti-neutrino, and an electron.

<sup>2</sup><https://physics.nist.gov/cuu/Constants/index.html>

| Particle               | Symbol        | Momentum | Spinor (up) | Spinor (down) |
|------------------------|---------------|----------|-------------|---------------|
| Muon                   | $\mu^-$       | $p_1$    | $u_{11}$    | $u_{12}$      |
| Muon neutrino          | $\nu_\mu$     | $p_2$    | $u_{21}$    | $u_{22}$      |
| Electron anti-neutrino | $\bar{\nu}_e$ | $p_3$    | $v_{31}$    | $v_{32}$      |
| Electron               | $e^-$         | $p_4$    | $u_{41}$    | $u_{42}$      |

We will use the following momentum vectors.

$$\begin{aligned}
 p_1 &= \begin{pmatrix} E_1 \\ p_{1x} \\ p_{1y} \\ p_{1z} \end{pmatrix} & p_2 &= \begin{pmatrix} E_2 \\ p_{2x} \\ p_{2y} \\ p_{2z} \end{pmatrix} & p_3 &= \begin{pmatrix} E_3 \\ p_{3x} \\ p_{3y} \\ p_{3z} \end{pmatrix} & p_4 &= \begin{pmatrix} E_4 \\ p_{4x} \\ p_{4y} \\ p_{4z} \end{pmatrix} \\
 \mu^- & & \nu_\mu & & \bar{\nu}_e & & e^-
 \end{aligned}$$

And we will use the following Dirac spinors.

$$\begin{aligned}
 u_{11} &= \begin{pmatrix} E_1 + m_1 \\ 0 \\ p_{1z} \\ p_{1x} + ip_{1y} \end{pmatrix} & u_{21} &= \begin{pmatrix} E_2 + m_2 \\ 0 \\ p_{2z} \\ p_{2x} + ip_{2y} \end{pmatrix} & v_{31} &= \begin{pmatrix} p_{3z} \\ p_{3x} + ip_{3y} \\ E_3 + m_3 \\ 0 \end{pmatrix} & u_{41} &= \begin{pmatrix} E_4 + m_4 \\ 0 \\ p_{4z} \\ p_{4x} + ip_{4y} \end{pmatrix} \\
 u_{12} &= \begin{pmatrix} 0 \\ E_1 + m_1 \\ p_{1x} - ip_{1y} \\ -p_{1z} \end{pmatrix} & u_{22} &= \begin{pmatrix} 0 \\ E_2 + m_2 \\ p_{2x} - ip_{2y} \\ -p_{2z} \end{pmatrix} & v_{32} &= \begin{pmatrix} p_{3x} - ip_{3y} \\ -p_{3z} \\ 0 \\ E_3 + m_3 \end{pmatrix} & u_{42} &= \begin{pmatrix} 0 \\ E_4 + m_4 \\ p_{4x} - ip_{4y} \\ -p_{4z} \end{pmatrix} \\
 \mu^- & & \nu_\mu & & \bar{\nu}_e & & e^-
 \end{aligned}$$

From the Feynman diagram above we have the following amplitude  $\mathcal{M}_{abcd}$  where each letter in  $abcd$  can be either 1 (spin up) or 2 (spin down).

$$\mathcal{M}_{abcd} = \frac{G_F}{\sqrt{N}} (\bar{u}_{4d} \gamma^\mu (1 - \gamma^5) v_{3c}) (\bar{u}_{2b} \gamma_\mu (1 - \gamma^5) u_{1a})$$

Symbol  $N$  is the following normalization constant.

$$N = (E_1 + m_1)(E_2 + m_2)(E_3 + m_3)(E_4 + m_4)$$

Recall that the magnitude squared of an amplitude is a probability density and also an observable.

$$|\mathcal{M}_{abcd}|^2 = \mathcal{M}_{abcd}^* \mathcal{M}_{abcd}$$

In a typical muon decay experiment the spins are not observed. Consequently, the experimental result is an average of spin states. The average is computed by summing over all spin states and dividing by four.

$$\langle |\mathcal{M}|^2 \rangle = \frac{1}{4} \sum_{a=1}^2 \sum_{b=1}^2 \sum_{c=1}^2 \sum_{d=1}^2 |\mathcal{M}_{abcd}|^2$$

The result is a simple formula.

$$\langle |\mathcal{M}|^2 \rangle = 64G_F^2 (p_1 \cdot p_3)(p_2 \cdot p_4) \quad (1)$$

In component notation we have

$$\langle |\mathcal{M}|^2 \rangle = 64G_F^2 \left( (p_1)^\alpha g_{\alpha\beta} (p_3)^\beta \right) \left( (p_2)^\gamma g_{\gamma\delta} (p_4)^\delta \right)$$

where

$$g_{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}$$
