## Template functions

Function f in d(f,x) does not have to be defined, it can be a template function with just a name and an argument list. The argument list determines the result. For example, d(f(x),x) evaluates to itself because f depends on x. However, d(f(x),y) evaluates to zero because f does not depend on g.

```
Example 1. f(x) depends on x. d(\mathbf{f}(\mathbf{x}), \mathbf{x}) d(f(x), x) Example 2. f(x) does not depend on y. d(\mathbf{f}(\mathbf{x}), \mathbf{y}) 0 Example 3. f(x, y) depends on both x and y. d(\mathbf{f}(\mathbf{x}, \mathbf{y}), \mathbf{y}) d(f(x, y), y) Example 4. f() is a wildcard that matches any symbol. d(\mathbf{f}(), \mathbf{t}) d(f(), t) Template functions are useful for working with differential forms. For example, show that \nabla \cdot (\nabla \times \mathbf{F}) = 0
```

F = (Fx(),Fy(),Fz())

div(curl(F))
