## Template functions

Function f in d(f,x) does not have to be defined, it can be a template function with just a name and an argument list. The argument list determines the result. For example, d(f(x),x) evaluates to itself because f depends on x. However, d(f(x),y) evaluates to zero because f does not depend on g.

```
Example 1. f(x) depends on x.

d(f(x), x)
d(f(x), x)
Example 2. f(x) does not depend on y.

d(f(x), y)
0

Example 3. f(x, y) depends on both x and y.

d(f(x, y), y)
d(f(x, y), y)
Example 4. f() is a wildcard that matches any symbol.

d(f(), t)
Template functions are useful for working with differential forms. For example, show that
```

 $\nabla \cdot (\nabla \times \mathbf{F}) = 0$ 

```
F = (Fx(),Fy(),Fz())
div(curl(F))
```
