## MUON PRODUCTION

A high energy electron and positron collision can create two muons.

Here is the same diagram with momentum and spinor labels.

In a typical collider experiment the momentum vectors are

$$p_{1} = \begin{pmatrix} E \\ 0 \\ 0 \\ p \end{pmatrix} \qquad p_{2} = \begin{pmatrix} E \\ 0 \\ 0 \\ -p \end{pmatrix} \qquad p_{3} = \begin{pmatrix} E \\ \rho \sin \theta \cos \phi \\ \rho \sin \theta \sin \phi \\ \rho \cos \theta \end{pmatrix} \qquad p_{4} = \begin{pmatrix} E \\ -\rho \sin \theta \cos \phi \\ -\rho \sin \theta \sin \phi \\ -\rho \cos \theta \end{pmatrix}$$

where E is beam energy,  $p = \sqrt{E^2 - m^2}$ ,  $\rho = \sqrt{E^2 - M^2}$ , m is electron mass 0.51 MeV, and M is muon mass 106 MeV. The spinors are

$$u_{11} = \begin{pmatrix} E + m \\ 0 \\ p \\ 0 \end{pmatrix} \quad v_{21} = \begin{pmatrix} -p \\ 0 \\ E + m \\ 0 \end{pmatrix} \quad u_{31} = \begin{pmatrix} E + M \\ 0 \\ p_3^z \\ p_3^x + ip_3^y \end{pmatrix} \quad v_{41} = \begin{pmatrix} p_4^z \\ p_4^x + ip_4^y \\ E + M \\ 0 \end{pmatrix}$$

$$u_{12} = \begin{pmatrix} 0 \\ E + m \\ 0 \\ -p \end{pmatrix} \quad v_{22} = \begin{pmatrix} 0 \\ p \\ 0 \\ E + m \end{pmatrix} \quad u_{32} = \begin{pmatrix} 0 \\ E + M \\ p_3^x - ip_3^y \\ -p_3^z \end{pmatrix} \quad v_{42} = \begin{pmatrix} p_4^x - ip_4^y \\ -p_4^z \\ 0 \\ E + M \end{pmatrix}$$

The last digit in a spinor subscript is 1 for spin up and 2 for spin down. Note that the spinors are not individually normalized. Instead, a combined spinor normalization constant  $N = (E + m)^2 (E + M)^2$  will be used where needed.

This is the probability density for muon production. Symbol  $s = (p_1 + p_2)^2 = 4E^2$ , symbol  $s_j$  selects the spin of spinor j, and e is electron charge.

$$|\mathcal{M}(s_1, s_2, s_3, s_4)|^2 = \frac{e^4}{s^2} \frac{1}{N} \left| (\bar{u}_3 \gamma_\mu v_4) (\bar{v}_2 \gamma^\mu u_1) \right|^2$$

The expected probability density  $\langle |\mathcal{M}|^2 \rangle$  is computed by summing  $|\mathcal{M}|^2$  over all spin states and dividing by the number of inbound states. There are four inbound states.

$$\langle |\mathcal{M}|^2 \rangle = \frac{1}{4} \sum_{s_1=1}^2 \sum_{s_2=1}^2 \sum_{s_3=1}^2 \sum_{s_4=1}^2 |\mathcal{M}(s_1, s_2, s_3, s_4)|^2$$
$$= \frac{e^4}{4s^2} \sum_{s_1=1}^2 \sum_{s_2=1}^2 \sum_{s_3=1}^2 \sum_{s_4=1}^2 \frac{1}{N} |(\bar{u}_3 \gamma_\mu v_4)(\bar{v}_2 \gamma^\mu u_1)|^2$$

Another way to compute  $\langle |\mathcal{M}|^2 \rangle$  is to use the Casimir trick.

$$\langle |\mathcal{M}|^2 \rangle = \frac{e^4}{4s^2} \operatorname{Tr} \left( (\not p_3 + M) \gamma^{\mu} (\not p_4 - M) \gamma^{\nu} \right) \operatorname{Tr} \left( (\not p_2 - m) \gamma_{\mu} (\not p_1 + m) \gamma_{\nu} \right)$$

Here is a third way to compute  $\langle |\mathcal{M}|^2 \rangle$ .

$$\langle |\mathcal{M}|^2 \rangle = \frac{e^4}{4s^2} \left( 32(p_1 \cdot p_3)(p_2 \cdot p_4) + 32(p_1 \cdot p_4)(p_2 \cdot p_3) + 32m^2(p_3 \cdot p_4) + 32M^2(p_1 \cdot p_2) + 64m^2M^2 \right)$$

For the momentum vectors given above the result is

$$\langle |\mathcal{M}|^2 \rangle = e^4 \left( 1 + \cos^2 \theta + \frac{m^2 + M^2}{E^2} \sin^2 \theta + \frac{m^2 M^2}{E^4} \cos^2 \theta \right)$$

The Stanford Linear Collider had a collision energy of 2E = 91 GeV. For beam energies such as SLC where  $E \gg M$  the above equation can be approximated as

$$\langle |\mathcal{M}|^2 \rangle = e^4 (1 + \cos^2 \theta)$$

The differential cross section is

$$\frac{d\sigma}{d\Omega} = \frac{\langle |\mathcal{M}|^2 \rangle}{64\pi^2 s} = \frac{e^4}{256\pi^2 E^2} (1 + \cos^2 \theta)$$

Recall that  $e^2 = 4\pi\alpha$  hence

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{16E^2} (1 + \cos^2 \theta)$$

The total cross section calculation requires the following definite integral.

$$\int_{\Omega} (1 + \cos^2 \theta) \, d\Omega = \int_{0}^{2\pi} \int_{0}^{\pi} (1 + \cos^2 \theta) \sin \theta \, d\theta \, d\phi = \frac{8}{3} \int_{0}^{2\pi} d\phi = \frac{16\pi}{3}$$

Hence the total cross section is

$$\sigma = \int_{\Omega} d\sigma = \int_{\Omega} \frac{\alpha^2}{16E^2} (1 + \cos^2 \theta) d\Omega = \frac{\alpha^2}{16E^2} \frac{16\pi}{3} = \frac{\pi \alpha^2}{3E^2}$$

We can integrate the differential cross section to obtain a cumulative distribution function.

Let

$$I(\xi) = 2\pi \int_0^{\xi} \frac{d\sigma}{d\Omega} \sin\theta \, d\theta, \qquad 0 \le \xi \le \pi$$

The result is

$$I(\xi) = 2\pi \left(\frac{\alpha^2}{16E^2}\right) \left(-\frac{1}{3}\cos^3 \xi - \cos \xi + \frac{4}{3}\right)$$

The cumulative distribution function is

$$F(\theta) = \frac{I(\theta)}{I(\pi)}, \qquad 0 \le \theta \le \pi$$

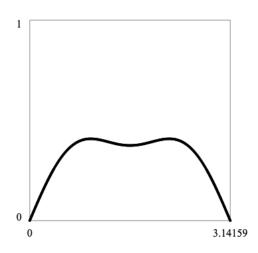

Hence

$$P(\theta_1 \le \theta \le \theta_2) = F(\theta_2) - F(\theta_1)$$

The normalized probability density is

$$f(\theta) = \frac{dF(\theta)}{d\theta} = \frac{3}{8}(1 + \cos^2 \theta)\sin \theta, \qquad 0 \le \theta \le \pi$$

Run "muon-production-5.txt" to draw the probability density function.

Run "muon-production-1.txt" to verify that

$$\frac{1}{N} \sum_{s_1=1}^{2} \sum_{s_2=1}^{2} \sum_{s_3=1}^{2} \sum_{s_4=1}^{2} \left| (\bar{u}_3 \gamma_{\mu} v_4) (\bar{v}_2 \gamma^{\mu} u_1) \right|^2 = \text{Tr} \left( (\not p_3 + M) \gamma^{\mu} (\not p_4 - M) \gamma^{\nu} \right) \text{Tr} \left( (\not p_2 - m) \gamma_{\mu} (\not p_1 + m) \gamma_{\nu} \right)$$

Run "muon-production-2.txt" to verify that

$$\frac{1}{64E^4} \operatorname{Tr} \left( (\not p_3 + M) \gamma^{\mu} (\not p_4 - M) \gamma^{\nu} \right) \operatorname{Tr} \left( (\not p_2 - m) \gamma_{\mu} (\not p_1 + m) \gamma_{\nu} \right)$$

$$= 1 + \cos^2 \theta + \frac{m^2 + M^2}{E^2} \sin^2 \theta + \frac{m^2 M^2}{E^4} \cos^2 \theta$$

and to verify that

$$\operatorname{Tr}\left((p_{3}+M)\gamma^{\mu}(p_{4}-M)\gamma^{\nu}\right)\operatorname{Tr}\left((p_{2}-m)\gamma_{\mu}(p_{1}+m)\gamma_{\nu}\right)$$

$$=32(p_{1}\cdot p_{3})(p_{2}\cdot p_{4})+32(p_{1}\cdot p_{4})(p_{2}\cdot p_{3})+32m^{2}(p_{3}\cdot p_{4})+32M^{2}(p_{1}\cdot p_{2})+64m^{2}M^{2}$$

This table shows SLAC-PEP muon pair production data obtained from HEP Data.<sup>1</sup>

Data x and y have the following relationship with cross section parameters.

$$x = \cos \theta$$
  $y = (2E)^2 \frac{d\sigma}{d\cos \theta}$ 

The differential cross section for muon production is

$$\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{16E^2} (1 + \cos^2 \theta)$$

Let us compute predicted values  $\hat{y}$  from the cross section formula. Start by finding the relationship between  $d\Omega$  and  $d\cos\theta$ . Since  $1+\cos^2\theta$  has no dependence on  $\phi$  we have

$$\int_{\Omega} (1 + \cos^2 \theta) d\Omega = \int_0^{2\pi} \int_0^{\pi} (1 + \cos^2 \theta) \sin \theta d\theta d\phi = 2\pi \int_0^{\pi} (1 + \cos^2 \theta) \sin \theta d\theta$$

Hence

$$d\Omega = 2\pi \sin\theta \, d\theta = -2\pi \, d\cos\theta$$

We want positive cross sections so drop the minus sign and set

$$\frac{d\sigma}{d\cos\theta} = 2\pi \frac{d\sigma}{d\Omega}$$

 $<sup>^1</sup>$ www.hepdata.net/record/ins216031 (Table 1, 29.0 GeV)

We can now write

$$y = (2E)^{2} \frac{d\sigma}{d\cos\theta}$$

$$= (2E)^{2} (2\pi) \frac{d\sigma}{d\Omega}$$

$$= (2E)^{2} (2\pi) \frac{\alpha^{2}}{16E^{2}} (1 + \cos^{2}\theta)$$

$$= \frac{\pi\alpha^{2}}{2} (1 + \cos^{2}\theta)$$

Multiply by  $(\hbar c)^2$  to convert to SI and multiply by  $10^{37}$  to convert square meters to nanobarns.

$$y = \frac{\pi\alpha^2}{2}(1 + \cos^2\theta) \times (\hbar c)^2 \times 10^{37}$$

Replace  $\cos \theta$  with explanatory variable x to obtain  $\hat{y}$ .

$$\hat{y} = \frac{\pi \alpha^2}{2} (1 + x^2) \times (\hbar c)^2 \times 10^{37}$$

Here are the predicted values  $\hat{y}$  based on the above formula.

x	y	$\hat{y}$
-0.925	67.08	60.44
-0.85	58.67	56.10
-0.75	54.66	50.89
-0.65	51.72	46.33
-0.55	43.70	42.42
-0.45	41.12	39.17
-0.35	39.71	36.56

0.85	49.28	56.10
0.925	55.70	60.44

The coefficient of determination  $\mathbb{R}^2$  measures how well predicted values fit the real data.

$$R^{2} = 1 - \frac{\sum (y - \hat{y})^{2}}{\sum (y - \bar{y})^{2}} = 0.87$$

The result indicates that the model  $d\sigma$  explains 87% of the variance in the data.

Run "muon-production-3.txt" to compute the above results.

The following differential cross section formula from electroweak theory results in a better fit to the data.<sup>2</sup>

$$\frac{d\sigma}{d\Omega} = F(s)(1 + \cos^2 \theta) + G(s)\cos \theta$$

where

$$F(s) = \frac{\alpha^2}{4s} \left( 1 + \frac{g_V^2}{\sqrt{2}\pi} \left( \frac{m_Z^2}{s - m_Z^2} \right) \left( \frac{sG}{\alpha} \right) + \frac{(g_A^2 + g_V^2)^2}{8\pi^2} \left( \frac{m_Z^2}{s - m_Z^2} \right)^2 \left( \frac{sG}{\alpha} \right)^2 \right)$$

$$G(s) = \frac{\alpha^2}{4s} \left( \frac{\sqrt{2}g_A^2}{\pi} \left( \frac{m_Z^2}{s - m_Z^2} \right) \left( \frac{sG}{\alpha} \right) + \frac{g_A^2 g_V^2}{\pi^2} \left( \frac{m_Z^2}{s - m_Z^2} \right)^2 \left( \frac{sG}{\alpha} \right)^2 \right)$$

and

$$g_A = -0.5$$
  
 $g_V = -0.0348$   
 $m_Z = 91.17 \,\text{GeV}$   
 $G = 1.166 \times 10^{-5} \,\text{GeV}^{-2}$ 

The corresponding formula for  $\hat{y}$  is

$$\hat{y} = 2\pi \left[ F(s)(1+x^2) + G(s)x \right] \times (\hbar c)^2 \times 10^{37}$$

where  $\sqrt{s}=29\,\mathrm{GeV}$  is the center of mass collision energy. Here are the predicted values  $\hat{y}$  based on the above formula.

The coefficient of determination  $\mathbb{R}^2$  is

$$R^{2} = 1 - \frac{\sum (y - \hat{y})^{2}}{\sum (y - \bar{y})^{2}} = 0.98$$

The result indicates that electroweak theory explains 98% of the variance in the data.

Run "compton-scattering-4.txt" to verify.

Here are a few notes about how the scripts work.

In component notation the traces become sums over the repeated index  $\alpha$ .

$$\operatorname{Tr}\left((\not p_3+M)\gamma^{\mu}(\not p_4-M)\gamma^{\nu}\right)=(\not p_3+M)^{\alpha}{}_{\beta}\gamma^{\mu\beta}{}_{\rho}(\not p_4-M)^{\rho}{}_{\sigma}\gamma^{\nu\sigma}{}_{\alpha}$$
$$\operatorname{Tr}\left((\not p_2-m)\gamma_{\mu}(\not p_1+m)\gamma_{\nu}\right)=(\not p_2-m)^{\alpha}{}_{\beta}\gamma_{\mu}{}^{\beta}{}_{\rho}(\not p_1+m)^{\rho}{}_{\sigma}\gamma_{\nu}{}^{\sigma}{}_{\alpha}$$

To convert the above formulas to Eigenmath code, the  $\gamma$  tensors need to be transposed so that repeated indices are adjacent to each other. Also, multiply  $\gamma^{\mu}$  by the metric tensor to lower the index.

$$\gamma^{\beta\mu}{}_{\rho}$$
  $\to$  gammaT = transpose(gamma)  $\gamma^{\beta}{}_{\mu\rho}$   $\to$  gammaL = transpose(dot(gmunu,gamma))

Define the following  $4 \times 4$  matrices.

Then

$$(\not\!\!p_3 + M)^\alpha{}_\beta \gamma^{\mu\beta}{}_\rho (\not\!\!p_4 - M)^\rho{}_\sigma \gamma^{\nu\sigma}{}_\alpha \quad \rightarrow \quad \text{T1 = contract(dot(X3,gammaT,X4,gammaT),1,4)}$$
 
$$(\not\!\!p_2 - m)^\alpha{}_\beta \gamma_\mu{}^\beta{}_\rho (\not\!\!p_1 + m)^\rho{}_\sigma \gamma_\nu{}^\sigma{}_\alpha \quad \rightarrow \quad \text{T2 = contract(dot(X2,gammaL,X1,gammaL),1,4)}$$

Next, multiply matrices and sum over repeated indices. The dot function sums over  $\nu$  then the contract function sums over  $\mu$ . The transpose makes the  $\nu$  indices adjacent as required by the dot function.

$$\operatorname{Tr}(\cdots \gamma^{\mu} \cdots \gamma^{\nu}) \operatorname{Tr}(\cdots \gamma_{\mu} \cdots \gamma_{\nu}) \rightarrow \operatorname{contract(dot(T1,transpose(T2)))}$$
