From "V minus A" theory we have the following formula for muon lifetime τ .

$$\tau = \frac{96\pi^2 h}{G_F^2 \left(m_\mu c^2\right)^5}$$

Symbol G_F is Fermi coupling constant, m_{μ} is muon mass.

From NIST² we have

$$G_F = 1.1663787 \times 10^{-5} \text{ GeV}^{-2}$$

 $m_{\mu} = 1.883531627 \times 10^{-28} \text{ kilogram}$
 $h = 6.62607015 \times 10^{-34} \text{ joule second (exact)}$
 $c = 299792458 \text{ meter second}^{-1} \text{ (exact)}$
 $1 \text{ eV} = 1.602176634 \times 10^{-19} \text{ joule (exact)}$

Hence

$$\tau = 2.18735 \times 10^{-6} \, \text{second}$$

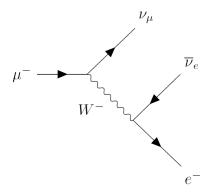

The result is a bit smaller than the PDG value.

$$\frac{\tau}{2.1969811 \times 10^{-6} \; \mathrm{second}} = 0.9956$$

A muon decays into a muon neutrino, an electron anti-neutrino, and an electron.

https://pdg.lbl.gov/2020/listings/rpp2020-list-muon.pdf

²https://physics.nist.gov/cuu/Constants/index.html

Particle		Symbol	Momentum	Spinor (up)	Spinor (down)
Muon		μ^-	p_1	u_{11}	u_{12}
Muon neutr	rino	$ u_{\mu}$	p_2	u_{21}	u_{22}
Electron an	ti-neutrino	$ar{ u}_e$	p_3	v_{31}	v_{32}
Electron		e^{-}	p_4	u_{41}	u_{42}

We will use the following momentum vectors.

$$p_{1} = \begin{pmatrix} E_{1} \\ p_{1x} \\ p_{1y} \\ p_{1z} \end{pmatrix} \qquad p_{2} = \begin{pmatrix} E_{2} \\ p_{2x} \\ p_{2y} \\ p_{2z} \end{pmatrix} \qquad p_{3} = \begin{pmatrix} E_{3} \\ p_{3x} \\ p_{3y} \\ p_{3z} \end{pmatrix} \qquad p_{4} = \begin{pmatrix} E_{4} \\ p_{4x} \\ p_{4y} \\ p_{4z} \end{pmatrix}$$

$$\mu^{-} \qquad \nu_{\mu} \qquad \bar{\nu}_{e} \qquad e^{-}$$

And we will also use the following Dirac spinors.

$$u_{11} = \begin{pmatrix} E_1 + m_1 \\ 0 \\ p_{1z} \\ p_{1x} + ip_{1y} \end{pmatrix} \qquad u_{21} = \begin{pmatrix} E_2 + m_2 \\ 0 \\ p_{2z} \\ p_{2x} + ip_{2y} \end{pmatrix} \qquad v_{31} = \begin{pmatrix} p_{3z} \\ p_{3x} + ip_{3y} \\ E_3 + m_3 \\ 0 \end{pmatrix} \qquad u_{41} = \begin{pmatrix} E_4 + m_4 \\ 0 \\ p_{4z} \\ p_{4x} + ip_{4y} \end{pmatrix}$$

$$u_{12} = \begin{pmatrix} 0 \\ E_1 + m_1 \\ p_{1x} - ip_{1y} \\ -p_{1z} \end{pmatrix} \qquad u_{22} = \begin{pmatrix} 0 \\ E_2 + m_2 \\ p_{2x} - ip_{2y} \\ -p_{2z} \end{pmatrix} \qquad v_{32} = \begin{pmatrix} p_{3x} - ip_{3y} \\ -p_{3z} \\ 0 \\ E_3 + m_3 \end{pmatrix} \qquad u_{42} = \begin{pmatrix} 0 \\ E_4 + m_4 \\ p_{4x} - ip_{4y} \\ -p_{4z} \end{pmatrix}$$

The energy terms are total energy.

$$E_1 = \sqrt{(p_{1x})^2 + (p_{1y})^2 + (p_{1z})^2 + m_1^2}$$

$$E_2 = \sqrt{(p_{2x})^2 + (p_{2y})^2 + (p_{2z})^2 + m_2^2}$$

$$E_3 = \sqrt{(p_{3x})^2 + (p_{3y})^2 + (p_{3z})^2 + m_3^2}$$

$$E_4 = \sqrt{(p_{4x})^2 + (p_{4y})^2 + (p_{4z})^2 + m_4^2}$$

From the Feynman diagram above we have the following amplitude \mathcal{M}_{abcd} where each letter in abcd can be either 1 (spin up) or 2 (spin down).

$$\mathcal{M}_{abcd} = \frac{G_F}{\sqrt{2}\sqrt{N}} \left(\bar{u}_{4d} \, \gamma^{\mu} (1 - \gamma^5) \, v_{3c} \right) \left(\bar{u}_{2b} \, \gamma_{\mu} (1 - \gamma^5) \, u_{1a} \right)$$

$$e^{-} \quad \bar{\nu}_e \quad \nu_{\mu} \quad \mu^{-}$$

Symbol N is the following spinor normalization constant.

$$N = (E_1 + m_1)(E_2 + m_2)(E_3 + m_3)(E_4 + m_4)$$

Recall that the magnitude squared of an amplitude is a probability density and also an observable.

$$|\mathcal{M}_{abcd}|^2 = \mathcal{M}^*_{abcd} \mathcal{M}_{abcd}$$

In a typical muon decay experiment the spins are not observed. Consequently, the experimental result is an average of spin states. The average is computed by summing over all spin states and dividing by the number of initial spin states. The muon has two spin states hence the divisor is two.

$$\langle |\mathcal{M}|^2 \rangle = \frac{1}{2} \sum_{a=1}^2 \sum_{b=1}^2 \sum_{c=1}^2 \sum_{d=1}^2 |\mathcal{M}_{abcd}|^2$$

The result is a simple formula.

$$\langle |\mathcal{M}|^2 \rangle = 64G_F^2(p_1 \cdot p_3)(p_2 \cdot p_4) \tag{1}$$

In component notation we have

$$\langle |\mathcal{M}|^2 \rangle = 64G_F^2 \bigg((p_1)^{\mu} g_{\mu\nu} (p_3)^{\nu} \bigg) \bigg((p_2)^{\mu} g_{\mu\nu} (p_4)^{\nu} \bigg)$$

where

$$g_{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}$$

Muon decay rate Γ is an average over all possible values of momentum. In the muon rest frame $p_1 = (m_1, 0, 0, 0)$ we have

$$\Gamma = \frac{(2\pi)^4}{2m_1} \int \langle |\mathcal{M}|^2 \rangle \, \delta(p_1 - p_2 - p_3 - p_4) \, \frac{d^3 p_2}{(2\pi)^3 2E_2} \, \frac{d^3 p_3}{(2\pi)^3 2E_3} \, \frac{d^3 p_4}{(2\pi)^3 2E_4}$$

It can be shown that

$$\Gamma = \frac{G_F^2 m_\mu^5}{192\pi^3}$$

where $m_{\mu} = m_1$. Muon lifetime τ is the inverse of decay rate.

$$\tau = \frac{1}{\Gamma} = \frac{192\pi^3}{G_F^2 m_\mu^5}$$

Converting from natural units to physical units yields

$$\tau = \frac{96\pi^2 h}{G_F^2 \left(m_\mu c^2\right)^5}$$

Probability density $\langle |\mathcal{M}|^2 \rangle$ can also be computed using the following Casimir trick.

$$\langle |\mathcal{M}|^2 \rangle = \frac{G_F^2}{4} \operatorname{Tr} \left(p_4 \gamma^{\mu} (1 - \gamma^5) p_3 \gamma^{\nu} (1 - \gamma^5) \right) \operatorname{Tr} \left(p_2 \gamma_{\mu} (1 - \gamma^5) p_1 \gamma_{\nu} (1 - \gamma^5) \right)$$

The slashed symbols are 4×4 matrices computed as

$$p\!\!\!/=p\cdot\gamma=p^0\gamma^0-p^1\gamma^1-p^2\gamma^2-p^3\gamma^3$$

For example,
