6-5. The integral over t_c in equation (6.28) can be performed approximately using the method of stationary phase. By studying the application of such a method to this integral, show that most of the contribution to the integral comes from values of t_c near the region $t_c = r_a/u$, the time at which the electron would arrive at the center of the atom if it moved in a classical manner.

$$K^{(1)}(b,a) = -\frac{i}{\hbar} \int K_0(b,c)V(c)K_0(c,a) d\tau_c$$

$$= -\frac{i}{\hbar} \int \int_0^T \left(\frac{m}{2\pi i\hbar (T-t_c)}\right)^{3/2} \exp\left(\frac{im|\mathbf{x}_b - \mathbf{x}_c|^2}{2\hbar (T-t_c)}\right)$$

$$\times V(\mathbf{x}_c) \left(\frac{m}{2\pi i\hbar t_c}\right)^{3/2} \exp\left(\frac{im|\mathbf{x}_c - \mathbf{x}_a|^2}{2\hbar t_c}\right) dt_c d^3\mathbf{x}_c \quad (6.28)$$

The phase of the exponential in (6.28) is

$$\phi(t_c) = \frac{|\mathbf{x}_b - \mathbf{x}_c|^2}{T - t_c} + \frac{|\mathbf{x}_c - \mathbf{x}_a|^2}{t_c}$$

Then for

$$t_c = \frac{T|\mathbf{x}_c - \mathbf{x}_a|}{|\mathbf{x}_b - \mathbf{x}_c| + |\mathbf{x}_c - \mathbf{x}_a|}$$

the phase is stationary, that is,

$$\phi'(t_c) = 0$$

From (6.30) and (6.31) with r_a and $r_b \gg |\mathbf{x}_c|$

$$|\mathbf{x}_c - \mathbf{x}_a| \approx r_a$$
$$|\mathbf{x}_b - \mathbf{x}_c| \approx r_b$$

Hence

$$t_c = \frac{Tr_a}{r_a + r_b}$$
